IBM Z DATATHON 2026 · SSF2026 · REAL-TIME AI FOR CRITICAL DECISIONS

Kavach

Stops UPI scams *inside* the transaction — by watching the payment, the money flow, and the scam call together.

In-transaction AI on IBM LinuxONE · Snap ML on the Telum on-chip AI accelerator

THE PROBLEM

Scam money leaves in seconds and is laundered in minutes

₹22,845 Cr

lost by Indians to cyber fraud in 2024 — a 206% jump over 2023.[1]

₹1,616 Cr

lost to "digital arrest" scams in just the first 9 months of 2024.[2]

24 lakh

Layer-1 mule accounts already reported to the national Suspect Registry.[1]

A victim on a fake "CBI" video call sends ₹50,000 over UPI. The receiving **mule** forwards it to the next account within minutes, then cashes out. By the time anyone reports it, the money is gone.

WHY TODAY'S DEFENCES MISS IT

Each signal alone looks innocent

Rules

"Amount > ₹20k to a new payee" catches only **28%** of scams while blocking **2%** of honest payments — and scammers simply split amounts.

Per-transaction ML

Sees one payment at a time. It cannot see that the receiver collected from 9 strangers today, or that the sender just got off a scam call.

After-the-fact

Batch analytics and complaint portals act after settlement. Recovery after layering through mule chains is rare.

Stopping scams needs **more context** and a decision **before money settles** — on every payment, not a sample.

SOLUTION

Three signals, one decision, in microseconds

① The payment

Amount vs. the sender's habits, first payment to this person, new device, odd hour, bursts of payments.

② The money flow

Mule graph features: receiver fan-in from first-time payers, pass-through (money out minutes after money in). Repeat offenders go on a **mule watchlist** and are frozen.

③ The scam call

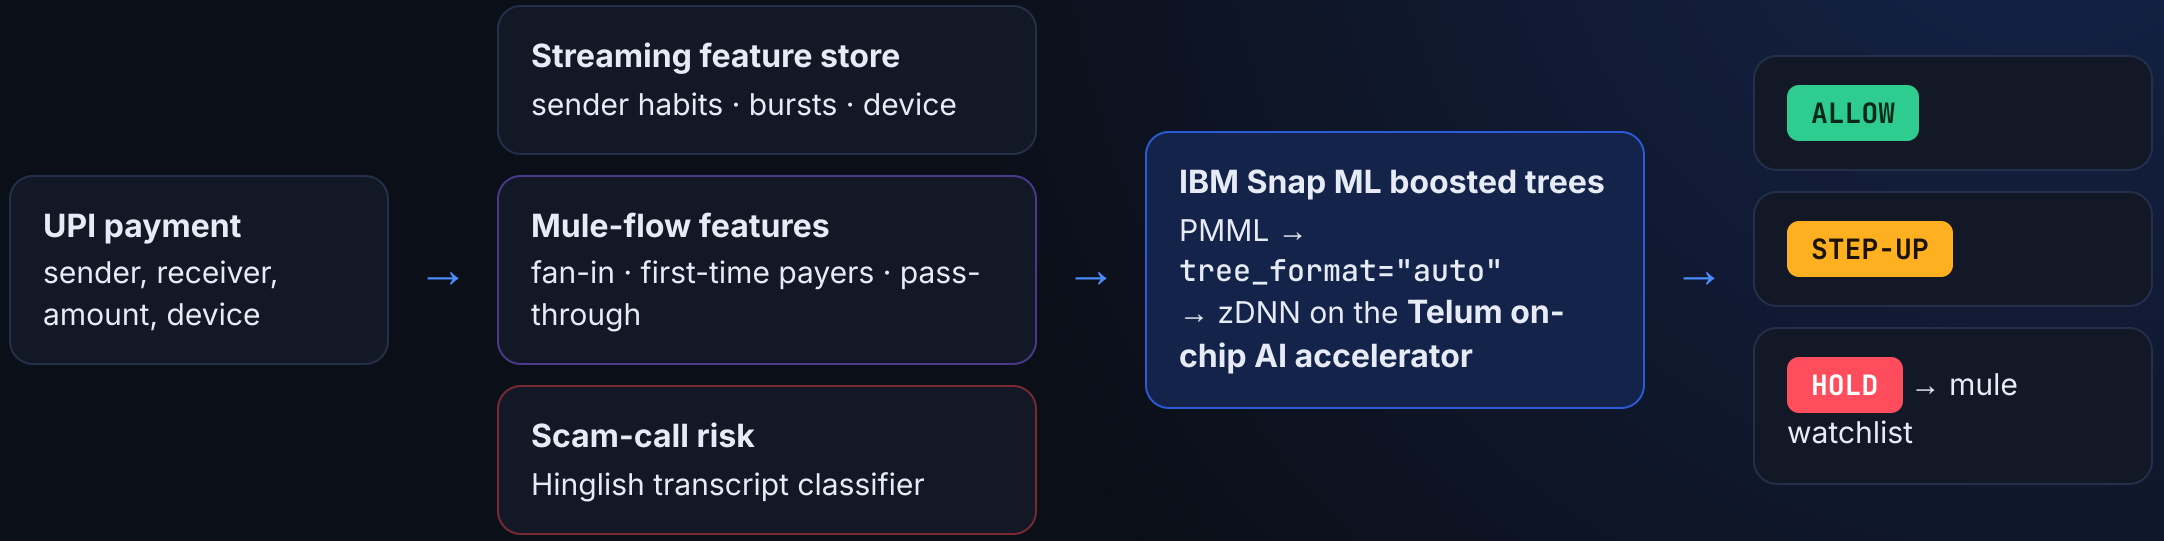

Hinglish call-transcript classifier spots "digital arrest", fake KYC, screen-share scripts. Risk attaches to the user for 2 hours.

ALLOW settle STEP-UP OTP + cooling-off + scam warning HOLD block, alert victim, notify bank

Every flag comes with plain-language reasons, e.g. "Scam call shortly before payment · Receiver collecting from many senders".

ARCHITECTURE

Scoring lives next to the payment, on IBM Z

One code path: the same streaming feature code builds training data and scores live payments, strictly from past events — no leakage, no training/serving skew. FastAPI + WebSocket dashboard; REST API for calls and payments.

WHY IBM Z / LINUXONE

Score 100% of payments in-line, where they already run

Telum on-chip AI accelerator

Snap ML compiles our trees to zDNN tensors on z16/z17, so inference runs on the processor chip next to the transaction workload — no network hop to a separate AI server.

Built and run on LinuxONE

Trained, benchmarked and served on a LinuxONE Community Cloud VM (s390x). One setup script; same model file falls back to CPU elsewhere.

Data never leaves the platform

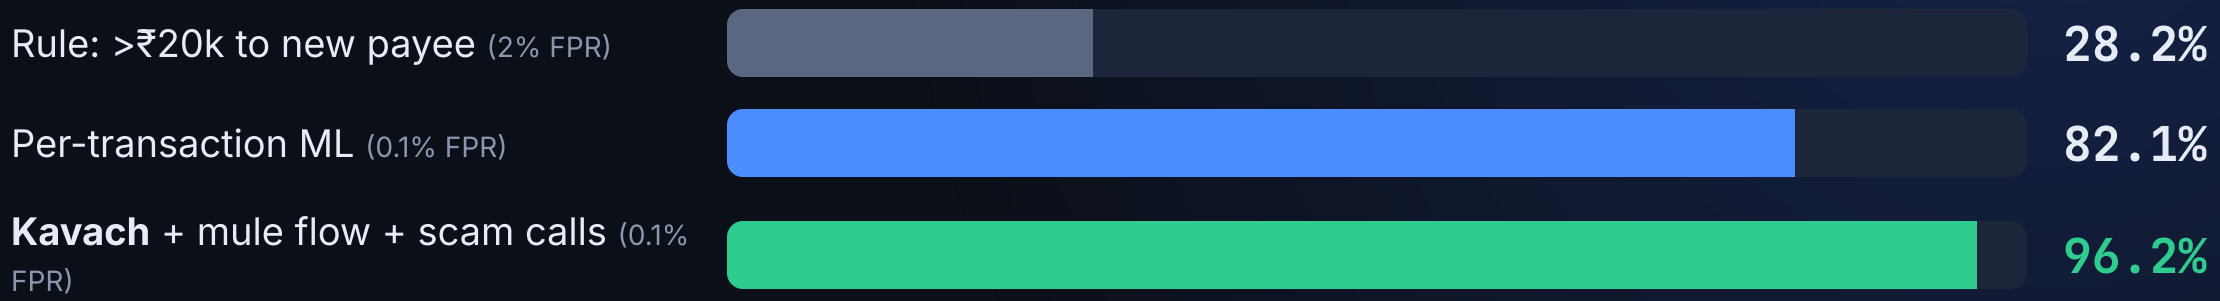

Payment and call data stay on Z with pervasive encryption. No external AI APIs, no data copies to a GPU cloud.

Scale & reliability

UPI does billions of payments a month with spikes at salary day and festivals. In-transaction AI must keep up with the core system itself — Z's throughput and uptime are made for this.

RESULTS · HELD-OUT DAYS, NEVER SEEN IN TRAINING

Same false-alarm budget, far more scams stopped

0.991
PR-AUC on 33,538 unseen payments (554 frauds)

26 µs
p50 full in-transaction path (features + model + decision), CPU baseline

0.06%
legit payments held in the live replay; 97% of fraud payments stopped

LIVE DEMO

Real-time dashboard: decisions, mule network, scam calls

Mule network — victim · watchlisted mule · suspect receiver

DATA & HONESTY

Synthetic, but built to be hard

Real UPI data with mule labels is not public, so we simulate a reproducible UPI world: **5,000 users**, merchants, kirana shops, **90 mules + 25 cash-out accounts**, 7 days, **~117k payments, ~14k calls**.

Scams: digital arrest, fake KYC, account takeover, ₹1 "test" payments, repeat victims, multi-hop layering.

Hard negatives on purpose

Friends pooling trip money then paying an agent minutes later · legit big first-time payments · phone changes · night owls · real bank fraud-alert calls · older mule accounts · scam calls seen for only 55% of victims.

Limits: call classifier trained on template Hinglish; watchlist rule is simple. Everything is reproducible with one command.

IMPACT & NEXT STEPS

From demo to a bank's payment switch

- Plugs into the bank / PSP authorisation path as a REST call — **no change for users** until risk is real.
- Cooling-off instead of hard blocks keeps honest users moving.
- Watchlist feeds the national **Suspect Registry**-style sharing between banks.
- Graph neural features over the full account graph.
- Federated training across banks without sharing raw data.
- On-device Hinglish ASR so call audio never leaves the phone.
- Benchmark at UPI scale on z17 with Spyre.

Kavach — the shield sits inside the payment, not after it.
